

Staking Volume Concentration by Stake Size

Only three of five stake-size tiers are present in this sample — no addresses staked less than 10 ETH, suggesting this dataset captures primarily mid-to-large stakers rather than the full retail range. Address count is dominated by the mid tier (100-1,000 ETH: 341 addresses, 68.2%), but volume tells a different story: the largest tier (1,000+ ETH) holds just 67 addresses (13.4%) yet accounts for roughly 4x the total volume of the mid tier — a concentration pattern consistent with what we saw in DEX trading data.

Active vs. Churned Stakers (30-Day Window)

Stakers by Status

Volume & Avg Stake by Status

41.2% of staker addresses (206) show no staking activity in the last 30 days ("churned"), while 58.8% (294) remain active. Despite being the smaller group, churned addresses account for over 70% of total staked volume — the average churned stake is substantially larger than the average active stake. This suggests "churn" here likely reflects large holders who staked once and hold long-term, rather than users abandoning the protocol — a pattern distinct from typical churn in consumer products like iGaming, where inactivity usually signals genuine disengagement.

Staking Behavior: Frequency vs. Stake Size Segments

Staker Segments: Count & Avg. Active Days

stake_size_segment	2. Fish (10-100 ETH)		3. Dolphin (100-1000 ETH)		4. Whale (>= 1000 ETH)		Total	
frequency_segment	num_stakers	avg_days_active	num_stakers	avg_days_active	num_stakers	avg_days_active	num_stakers	avg_days_active
1. Single Stake	58	1,00	206	1,00	33	1,00	297	3,00
2. Few (2-5)	30	20,10	123	17,30	26	16,20	179	53,60
3. Moderate (6-20)	4	46,80	11	41,80	4	41,50	19	130,10
4. High (>20)			1	52,00	4	62,30	5	114,30
Total	92	67,90	341	112,10	67	121,00	500	301,00

A clear monotonic relationship emerges: staking frequency, not stake size, is the strongest predictor of engagement duration.

"Single Stake" addresses (297 of 500, 59%) remain active for just 1-3 days on average across all stake sizes — consistent with one-off deposits rather than genuine engagement. In contrast, "High" frequency stakers (only 5 addresses total) remain active 114+ days on average, a 40x longer lifespan despite representing under 1% of the sample.

Stake size alone shows a much weaker signal: even among "Whale" tier (67 addresses), avg_days_active only reaches 121 days overall, driven almost entirely by the small number of frequent stakers within that tier — not by wallet size itself.

This challenges an intuitive assumption: one might expect whales to be inherently "stickier" due to larger capital commitment, but the data suggests behavioral frequency — not capital size — drives retention. A practical implication: engagement campaigns targeting "whale" wallets alone may miss the smaller cohort of frequent stakers who actually show the strongest loyalty signal.

Stakers by Frequency & Stake Size

Staking Cohort Size & Retention Over Time

Cohort size peaked in the earliest observation week (24 stakers) and declined steadily through July-August, consistent with left-censoring of the 90-day window rather than a genuine drop in new staker acquisition.

Avg. stakes-per-active-day shows a mild upward drift in the most recent cohorts (reaching ~1.3-1.4 in early August vs. ~0.85-1.0 in June-July). However, this should be read with caution: the latest cohorts contain only 1-2 stakers each, so the apparent increase may reflect small-sample noise rather than a genuine behavioral shift. A larger sample or a longer observation window would be needed to confirm whether staking intensity is actually rising over time.

Staker Engagement Duration Distribution

The majority of stakers (75.4%, 377 addresses) remain engaged for less than one week, consistent with one-off deposits rather than sustained participation. Only 12.4% stay active for 1-4 weeks, 12% for 1-3 months, and just one address (0.2%) shows engagement beyond 3 months.

However, staking intensity reveals the opposite pattern: that single 3+ month address stakes at roughly 14 times per active day — dramatically higher than any other engagement bucket (all under 2 stakes/day). This means the small handful of long-term stakers aren't just present longer, they're staking far more frequently once engaged. Combined with the Behavior Matrix findings, this reinforces a consistent pattern across the dataset: staking frequency, not duration or stake size alone, is the strongest signal of a highly engaged user — while the vast majority of participants remain one-off, low-intensity depositors.
