Totals	180.174.779.660,52

Volume concentration is extreme at the top: the single largest address (\$40B) represents over 22% of total observed volume, more than double the next nine addresses combined.

Trading activity follows a clear inverse pattern: high-frequency addresses (100K+ trades) execute small average tickets, consistent with automated market-making or routing bots, while low-frequency addresses show ticket sizes orders of magnitude larger — typical of manual, high-value trading. The top 20 addresses alone account for over \$85B of the \$180B total volume observed.

Total Unique Traders

500

Cohort Size & Retention Over Time.

Cohort defined by first trade within the 90-day observation window, not lifetime first trade.

The first observation week (2026-23) captured the majority of addresses (400+), reflecting that most traders in this dataset were already active before the 90-day window began — cohorts here measure "first trade within window," not lifetime onboarding. Retention (avg. active days) peaks in weeks 2026-25 to 2026-26 before declining toward the end of the window, consistent with natural right-censoring of recently-joined cohorts.

Average Volume per Trader by Cohort

Average volume per trader varies non-monotonically across cohorts (no clear rise or decline over time), indicating that high-value traders entered the data set at random points during the observation window rather than clustering in any particular period.

Trader Distribution by Activity Level

62.8% of addresses (314) fall into the highest activity bucket (100K+ trades per 90 days) — a strong signal that most "traders" in raw DEX data are actually bots, routers, or market-makers rather than individual retail users.

Trading Volume by Activity Bucket

Despite representing only 25.6% of addresses, the 10K–100K trade bucket generates nearly as much volume as the 100K+ bucket — showing that trading volume is driven both by frequency (bots) and by ticket size (fewer, larger manual trades), not frequency alone.
